### Trees: definition and implementation in Matlab

#### 1 empty T is a tree

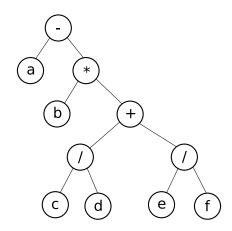

- If T is not empty, a T has exactly one node designated as the root(T)
- 3 the remaining nodes (T root(T)) of a tree are partitioned into *m* disjoint sets  $T_1, \ldots, T_m$ . Each of these are in turn a tree, and are called subtrees of *T*.

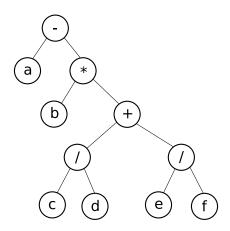

Tree arity *m* defines max amount of subtrees ( $m = 1 \rightarrow$  linked list,  $m = 2 \rightarrow$  binary tree)

```
classdef treeNode < handle
  properties
    key
    left
    right
  end
end</pre>
```

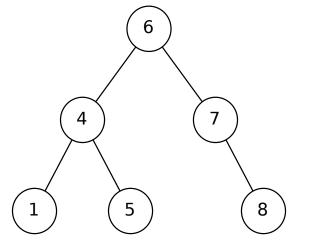

$$a-b*(c/d+e/f)$$

Example: tree traversal schemes; inorder, preorder and postorder

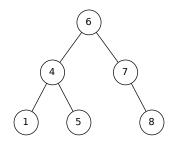

## Binary search trees (BST)

#### BST search time / balanced case

• Each level: 1 comparison  $\rightarrow 1/2$  remaining nodes "discarded"

• Find complexity:  $O(\log_2 n)$ 

## Extremely unbalanced tree

hus

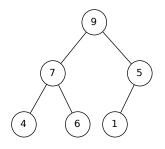

- Insert: O(n) (can be lower in balanced case)
- Delete current node: O(1)
- Search / balanced case:  $O(\log n)$
- Search / unbalanced case: O(n)

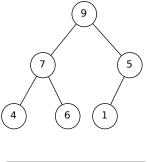

Balanced tree: every level of depth x (except last) has exactly 2<sup>x</sup> nodes

Heap property: the key of each node is maximum that of its parent

 $i^{th}$  element of  $j^{th}$  level is located in the index  $2^j + (i - 1)$ 

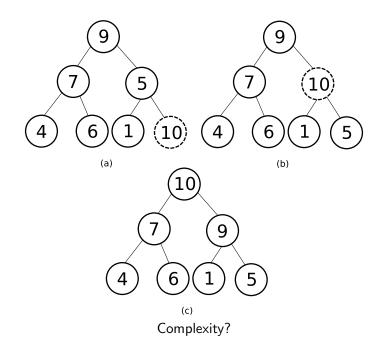

When inserting a new node, it becomes:

- Last node of the last layer, if there is space
- First node of a new layer (depth increases by 1)
- $\Rightarrow$  possible violation of the heap property

• Only the root node can be deleted

 $\implies$  priority queue semantics that is very useful in various cases (e.g. queueing elements that some have always priority over others)

 Elegant data structure with many applications, e.g. Dijkstra's shortest path algorithm and Heapsort

### Deleting from the heap

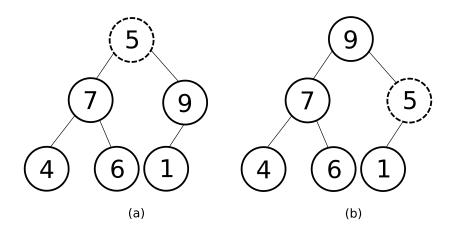

The root node is deleted and replaced with the last node

- $\rightarrow$  heap balanced, but heap property violated
- $\rightarrow \mathsf{heapify}(\mathsf{root})$

# heapify

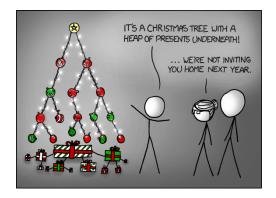

#### function H = heapify(H, n, endIndex)

```
largest = 0;
  I = left(n);
  r = right(n);
  if (| <= endlndex \& H(|) > H(n))
    |argest = |:
  else
    largest = n;
  end
  if (r \le endIndex \& H(r) > H(largest))
    largest = r;
  end
  if (largest != n)
    H = swap(H, largest, n); \% pseudo-code
    H = heapify(H, largest, endIndex);
  end
end
```

### Complexity of heap operations

■ Insert/delete:  $O(\log n)$ 

• Search max: O(1)

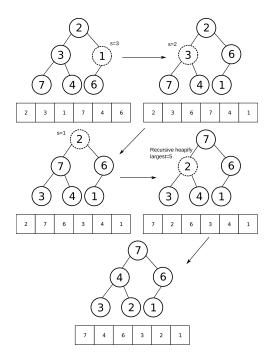

Step 1: turning an arbitrary array into a heap

Let's heapsort [2 3 1 7 4 6]

```
function A = buildHeap(A)

s = floor(length(A)/2);

while (s > 0)

A = heapify(A, s, length(A));

s = s - 1;

end

end
```

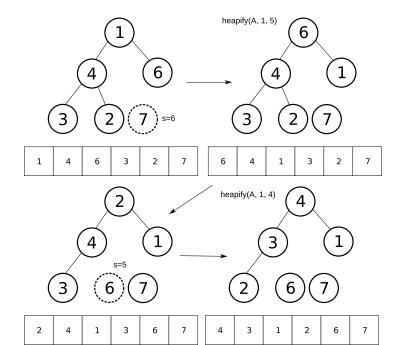

Assuming procedures (which we do not have in Matlab):

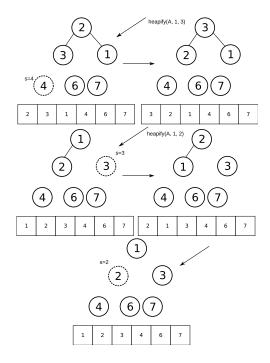

- *n*/2 iterations of while-loop
- *n*-node heap has at most  $\lceil n/2^{h+1} \rceil$  nodes of height *h*
- heapify with heap of height h is O(h)

$$\Rightarrow \sum_{h=0}^{\lfloor \log_2 n \rfloor} \lceil \frac{n}{2^{h+1}} \rceil O(h) = O\left(n \sum_{h=0}^{\lfloor \log_2 n \rfloor} \frac{h}{2^h}\right) = O(n2) = O(n)$$

```
function A = heapSort(A)
s = length(A);
% until s == 2, but this is a safer condition
while (s > 1)
% pseudo-code
A = swap(A, 1, s);
A = heapify(A, 1, s);
s = s - 1;
end
end
```

- Initial build heap: O(n)
- heapSort: *n* iterations of heapify, each  $O(\log n)$

• Total: 
$$O(n) + O(n \log n) = O(n \log n)$$

And does the sorting in place!
